KPI Definition Sheet

Week 3 • Healthcare Operations & Financial Intelligence Dashboard • Track A: Data Analytics

Each KPI below is defined so that another analyst can rebuild it. The values are the current figures on the dashboard. Measures are written in DAX and table names refer to the Power BI data model.

KPI 1: Total Encounters	27,891
Definition	The number of encounter records in the dataset. Each row of encounters.csv is one encounter, so this is a simple row count.
Calculation	`Total Encounters = COUNTROWS( encounters )`
Source field	encounters.csv, one row per encounter (ID).
Read with care	Includes all years. 2022 holds only 220 encounters and looks incomplete.

KPI 2: Total Claim Cost	$101.51M
Definition	The total amount billed across all encounters.
Calculation	`Total Claim Cost = SUM( encounters[TOTAL_CLAIM_COST] )`
Source field	encounters.csv, TOTAL_CLAIM_COST.
Read with care	This is the billed amount, not what was collected. It is different from the base encounter cost.

KPI 3: Payer Coverage	$31.10M
Definition	The part of the total claim cost that payers covered.
Calculation	`Payer Coverage = SUM( encounters[PAYER_COVERAGE] )`
Source field	encounters.csv, PAYER_COVERAGE.
Read with care	13,586 encounters have zero recorded coverage, so about half of all encounters add nothing to this figure.

KPI 4: Patient Responsibility	$70.42M
Definition	The part of the total claim cost not covered by payers. It is worked out as Total Claim Cost minus Payer Coverage, and it is about 69% of all claims.
Calculation	`Patient Responsibility = [Total Claim Cost] - [Payer Coverage]`
Source field	Derived from KPI 2 and KPI 3.
Read with care	This is a derived figure. It may include amounts later written off or paid another way, so it is not proof of unpaid debt.

KPI 5: Long-Stay Visits	58 (0.21%)
Definition	The number of encounters that lasted longer than 24 hours. Duration is STOP minus START, after both columns were converted from text to Date/Time in Power Query.
Calculation	`Long-Stay Visits = CALCULATE( COUNTROWS( encounters ), encounters[Duration_Hours] > 24 )`
Source field	encounters.csv, START and STOP (converted to Date/Time).
Read with care	Only valid where both timestamps are valid. Divide by Total Encounters to get the share.
